a Kits contain enough control template and primer mix for 5 control reactions. Catalog # 200514 contains enough reagents for 30 reactions total (control and experimental reactions combined). Catalog # 200515 contains enough reagents for 10 reactions total (control and experimental reactions combined).

b The composition of the reaction buffer and of the dNTP mix is proprietary. These reagents have been optimized for the QuikChange Multi site-directed mutagenesis protocols and have been qualified for use in conjunction with the other kit components. Do not substitute with buffers or dNTP mixes provided with other Stratagene kits.

c Thaw the dNTP mix and reaction buffer once, prepare single-use aliquots, and store the aliquots at –20°C.

d Do not subject the dNTP mix to multiple freeze-thaw cycles.

NOTICES TO PURCHASER

Use of the QuikChange Multi Site-Directed Mutagenesis Kit, catalog #200514 and catalog #200515, by commercial entities requires a commercial license from Agilent Technologies Inc., Stratagene Products Division.

The QuikChange Multi Site-Directed Mutagenesis Kit, catalog #200513, is presently offered for sale to commercial entities with a limited use license.

Notice to Purchaser: Limited License

Purchase of this product includes an immunity from suit under patents specified in the product insert to use only the amount purchased for the purchaser’s own internal research. No other patent rights (such as 5’ Nuclease Process patent rights) are conveyed expressly, by implication, or by estoppel. Further information on purchasing licenses may be obtained by contacting the Director of Licensing, Applied Biosystems, 850 Lincoln Centre Drive, Foster City, California 94404, USA.
INTRODUCTION

The QuikChange Multi Site-Directed Mutagenesis Kit offers a rapid and reliable method for site-directed mutagenesis of plasmid DNA at up to five different sites simultaneously. A single mutagenic oligonucleotide is required to mutagenize each site, using a double-stranded DNA template and following the one-day, three-step procedure outlined in Figure 1.

Site-Directed Mutagenesis Overview

*In vitro* site-directed mutagenesis is an invaluable technique for studying gene and protein structure-function relationships and for modifying vector sequences to facilitate cloning and expression strategies. Several approaches to this technique have been published, but these methods generally require the use of single-stranded DNA (ss-DNA) template, generally allow mutagenesis at only one site per round, and are labor intensive and technically difficult. The original Stratagene QuikChange Site-Directed Mutagenesis Kit eliminated the need for subcloning into M13-based bacteriophage vectors and for ss-DNA rescue, making site-directed mutagenesis studies simple and reliable, allowing oligo-mediated introduction of site-specific mutations into virtually any double-stranded plasmid DNA.

**FIGURE 1** Overview of the QuikChange Multi Site-Directed Mutagenesis method.

1. **Mutant Strand Synthesis**
   - Perform thermal cycling to:
     - Denature DNA template
     - Anneal mutagenic primers (all primers bind same strand)
     - Extend primers and ligate nicks with the QuikChange Multi enzyme blend

2. **Dpn I Digestion of Template**
   - Digest methylated and hemimethylated DNA with restriction enzyme *Dpn I*

3. **Transformation**
   - Transform mutated ssDNA into XL10 Gold ultracompetent cells
* Patent pending.
** U.S. Patent Nos. 5,789,166, 5,932,419, 6,391,548 and patents pending.
The QuikChange Multi site-directed mutagenesis system offers the same benefits of speed, simplicity and reliability afforded by the original QuikChange kit, but is based on a completely novel technology with distinct advantages. The novel technology of the QuikChange Multi system allows mutagenesis at multiple sites in a single round, using a single oligonucleotide per site. The QuikChange Multi site-directed mutagenesis system also makes it easy to randomize key amino acids using oligos containing degenerate codons. No specialized vectors or unique restriction sites are needed to use the QuikChange Multi kit—virtually any plasmid of up to 8 kb is a suitable template. The rapid three-step procedure introduces mutations at three different sites simultaneously in the 4-kb QuikChange Multi control plasmid with greater than 50% efficiency.

**Note** The QuikChange Multi site-directed mutagenesis system is recommended for mutating base pairs. To perform insertions or deletions, use the QuikChange II kit (Stratagene Catalog #200524) or QuikChange II XL kit (Stratagene Catalog #200522).

**Outline of the Three-Step Protocol**

The three-step QuikChange Multi site-directed mutagenesis method is outlined in Figure 1. Step 1 uses a thermal cycling procedure to achieve multiple rounds of mutant strand synthesis. Components of the thermal cycling reaction include a supercoiled double-stranded DNA template, two or more synthetic oligonucleotide primers containing the desired mutations, and the kit-provided enzyme blend featuring *PfuTurbo* DNA polymerase.*** First the mutagenic primers are annealed to denatured template DNA. (Note that all oligonucleotides are designed to bind the same strand of the template DNA.) *PfuTurbo* DNA polymerase then extends the mutagenic primers with high fidelity and without primer displacement, generating ds-DNA molecules with one strand bearing multiple mutations and containing nicks. The nicks are sealed by components in the enzyme blend.

In Step 2 of the procedure, the thermal cycling reaction products are treated with the restriction endonuclease *Dpn I*. The *Dpn I* endonuclease (target sequence: 5’-GmATACTC-3’) is specific for methylated and hemimethylated DNA and is used to digest the parental DNA template. DNA isolated from almost all *Escherichia coli* strains is dam methylated and therefore susceptible to digestion.

***U.S. Patent Nos. 7,045,328, 6,734,293, 6,489,150, 6,444,428, 6,183,997, 5,948,663, 5,866,395, 5,545,552, and patents pending.

1 *PfuTurbo* DNA polymerase has 6-fold higher fidelity in DNA synthesis than *Taq* DNA polymerase.
In Step 3, the reaction mixture, enriched for multiply mutated single stranded DNA, is transformed into XL10-Gold ultracompetent cells, where the mutant closed circle ss-DNA is converted into duplex form \textit{in vivo}. Double stranded plasmid DNA may then be prepared from the transformants and analyzed by appropriate methods to identify clones bearing each of the desired mutations.

\textbf{Note} \textit{While plasmid DNA isolated from almost all of the commonly used E. coli strains (dam$^+$) is methylated and is a suitable template for mutagenesis, plasmid DNA isolated from the exceptional dam$^-$ E. coli strains, including JM110 and SCS110, is not suitable.}

**Engineered Mutant Clone Collections Applications**

The QuikChange Multi site-directed mutagenesis system is well suited for constructing a diverse collection of engineered mutant clones to allow detailed protein structure-function analysis. The mutant clone collection may be constructed by performing site-specific saturation mutagenesis using primers containing degenerate nucleotides at 1–3 specific sites. For example, the system may be used to create mutant collections containing all possible amino acids at one site as well as combinations of different amino acids at multiple sites.

A collection of mutants can be created in a single QuikChange Multi kit reaction and then screened for mutants with improved activity using the appropriate functional assay. The QuikChange Multi kit overcomes issues associated with mutagenesis methods that employ mutagenic primers corresponding to both strands of DNA, where representation of mutants in the collection may be limited by the preferential binding of complementary strands of mutagenic primers to each other. See Appendix: Guidelines for Creating Engineered Mutant Clone Collections for additional information on using the kit for this application.
**QUIKCHANGE MULTI MUTAGENESIS CONTROL**

The QuikChange Multi control template and control primer mix are used to test the efficiency of simultaneous site-directed mutagenesis at three independent sites. The 4-kb control template is derived from the pBluescript II SK(–) phagemid that encodes the first 146 amino acids of β-galactosidase (encoded by the LacZ gene). The LacZ gene product is responsible for the production of blue colonies when appropriate *E. coli* transformants are grown on media containing X-gal (a chromogenic substrate of β-galactosidase) in the presence of the inducer IPTG. The QuikChange Multi control template was modified to contain stop codons at three positions in the LacZ coding sequence (see Figure 2). XL10-Gold cells transformed with the control template appear white on LB–ampicillin agar plates containing IPTG and X-gal, because each of the three mutations prevents the production of active β-galactosidase. The QuikChange Multi control primer mix contains three primers, each of which reverts one of these stop codons to the codon found in the original LacZ gene from pBluescript II SK(–) (see Figure 2). Restoration of active β-galactosidase requires that all three reversion events occur in the same molecule. Following transformation, colonies can be scored for the β-galactosidase (β-gal+, blue) phenotype, where a blue colony indicates the production of a triple-mutant plasmid.

![Figure 2](image_url)

**FIGURE 2** QuikChange Multi control plasmid and control primer sequences. A partial sequence of the LacZ coding region is shown, beginning with the ATG used for translation initiation. The QuikChange Multi control primer sequences are shown above their corresponding sites in the control plasmid, with the stop codons reverted by the control mutagenesis reaction boxed.
Notes

Mutagenic primers can be designed using our web-based QuikChange Primer Design Program available online at http://www.stratagene.com/qcprimerdesign.

When creating Engineered Mutant Clone collections, see Appendix: Guidelines for Creating Engineered Mutant Clone Collections for additional mutagenic primer design suggestions.

The QuikChange Multi site-directed mutagenesis system is recommended for mutating base pairs. To perform insertions or deletions, use the QuikChange II kit (Stratagene Catalog #200524) or QuikChange II XL kit (Stratagene Catalog #200522).

The mutagenic oligonucleotide primers must be designed individually to incorporate the desired point mutation or degenerate codon. The following considerations should be made when designing mutagenic primers:

1. All of the primers used for simultaneous mutagenesis must anneal to the same strand of the template plasmid. In most cases, primers binding to either strand will be incorporated into mutant plasmids with equal efficiency. However, certain secondary structures or features may influence the efficiency of the mutagenesis reaction. If a low mutagenesis efficiency (<30%) is observed, synthesize primers corresponding to the opposite strand of the plasmid.

2. Primers may be designed to bind to adjacent sequences or to well-separated regions on the same strand of the template plasmid. We have not observed any primer spacing-dependent effects on multiple mutagenesis efficiency.
3. Primers should be between 25 and 45 bases in length, with a melting temperature (Tm) of ≥75°C. Primers longer than 45 bases may be used, but using longer primers increases the likelihood of secondary structure formation, which may affect the efficiency of the mutagenesis reaction. Optimum primer sets for simultaneous mutagenesis should have similar melting temperatures. The following formula is commonly used for estimating the Tm of primers:

\[ T_m = 81.5 + 0.41(\%GC) - 675/N - \% \text{mismatch} \]

For calculating \( T_m \):
- \( N \) is the primer length in bases
- values for \( \% \text{GC} \) and \( \% \text{mismatch} \) are whole numbers

**Note** When using primer design software for QuikChange site-directed mutagenesis applications, be aware that the \( T_m \) calculated by the primer design software may differ from the \( T_m \) value calculated using the formula presented above. We recommend verifying primer \( T_m \)'s using the formula above or by using the QuikChange \( T_m \) calculator, available online at [http://www.stratagene.com](http://www.stratagene.com).

4. The desired point mutation or degenerate codon should be close to the middle of the primer with ~10–15 bases of template-complementary sequence on both sides.

5. Optimum primers have a minimum GC content of 40% and terminate in one or more C or G bases at the 3’-end.

6. Primers for simultaneous mutagenesis should be added to the mutagenesis reaction in approximately equimolar amounts. The mutagenesis reaction protocol in *Protocols* assumes that all primers used together are of similar length. If primers are >20% different in length, amounts of each primer added should be adjusted accordingly. For example, if primer 1 is 25 bases and primer 2 is 35 bases (a length ratio of 1:1.4), use 100 ng of primer 1 and 140 ng of primer 2.

To calculate the amount of each oligo in the reaction (in picomoles) use the following equation:

\[ X \ \text{pmoles of oligo} = \frac{\text{ng of oligo}}{330 \times \# \text{of bases in oligo}} \times 1000 \]

For example:
7. PAGE purification of primers is not necessary in all cases; however, 
\[
\frac{100 \text{ ng of oligo}}{330 \times 25 \text{ bases}} \times 1000 = 12 \text{ pmole}
\]
incomplete primer synthesis may result in a low mutagenesis efficiency 
and PAGE purification of the full-length primers may be beneficial.

**Protocols**

**Note** For suggestions on adapting the QuikChange Multi kit to create 
Engineered Mutant Clone collections, see Appendix: Guidelines 
for Creating Engineered Mutant Clone Collections.

**Mutant Strand Synthesis Reaction (Thermal Cycling)**

**Notes** Ensure that the plasmid DNA template is isolated from a dam\(^+\) 
E. coli strain. The majority of the commonly used E. coli strains 
are dam\(^+\). Plasmid DNA isolated from dam\(^-\) strains (e.g. JM110 
and SCS110) is not suitable.

To maximize temperature-cycling performance, we strongly 
recommend using thin-walled tubes, which ensure ideal contact 
with the temperature cycler’s heat blocks. The following protocols 
were optimized using thin-walled tubes.

Mutagenic primers should be added in approximately equimolar 
amounts. If primer lengths differ significantly (>20% difference), 
adjust the amounts of individual primers added in step 2 
accordingly.

1. Prepare the ds-DNA template either by standard miniprep protocols 
(e.g. StrataPrep Plasmid Miniprep Kit, Stratagene Catalog #400761) or 
by cesium chloride gradient purification.

2. Prepare the mutant strand synthesis reactions for thermal cycling as 
indicated below. Add the components in the order listed then mix 
gently by pipetting or tapping the reaction tube.

3. If the thermal cycler to be used does not have a hot-top assembly, overlay each reaction with ~30 µl of mineral oil.

4. Cycle the reactions using the cycling parameters outlined in the table below. (For the control reaction, use an 8-minute extension time.)

5. Following temperature cycling, place the reaction on ice for 2 minutes to cool the reaction to ≤37°C.

**Dpn I Digestion of the Amplification Products**

*Note* If a mineral oil overlay was used for amplification, it is important to insert the pipet tip below the mineral oil when adding the Dpn I enzyme to the reaction tubes or when transferring the 1.5 µl of the Dpn I-treated DNA to the transformation reaction. Using aerosol-resistant pipet tips, which are small and pointed, can facilitate this process.

1. Add 1 µl of *Dpn* I restriction enzyme (10 U/µl) directly to each amplification reaction (below the mineral oil overlay, if used) using a small, pointed pipet tip.

2. Gently and thoroughly mix each reaction mixture by pipetting the solution up and down several times. Spin down the reaction mixtures in a microcentrifuge for 1 minute, then immediately incubate reactions at 37°C for 1 hour to digest the parental (nonmutated) ds-DNA.
Transformation of XL10-Gold Ultracompetent Cells

**Note** Please see Transformation Guidelines for detailed information about parameters that affect transformation of XL10-Gold ultracompetent cells.

XL10-Gold cells are resistant to tetracycline and chloramphenicol. If the mutagenized plasmid contains only the tet<sup>+</sup> or cam<sup>+</sup> resistance marker, an alternative strain of competent cells must be used.

1. Gently thaw the XL10-Gold ultracompetent cells on ice. For each mutagenesis reaction, aliquot 45 μl of the ultracompetent cells to a prechilled 14-ml BD Falcon polypropylene round-bottom tube.

2. Add 2 μl of the β-ME mix provided with the kit to the 45 μl of cells. Using an alternative source of β-ME may reduce transformation efficiency.

3. Swirl the contents of the tube gently. Incubate the cells on ice for 10 minutes, swirling gently every 2 minutes.

4. Transfer 1.5 μl of the Dpn I-treated DNA from each mutagenesis reaction to a separate aliquot of the ultracompetent cells.

   **Note** Carefully remove any residual mineral oil from the pipet tip before transferring the Dpn I-treated DNA to each reaction.

   **Optional** Verify the transformation efficiency of the XL10-Gold ultracompetent cells by adding 1 μl of 0.01 ng/μl pUC18 control plasmid (dilute the provided pUC18 DNA 1:10) to another 45-μl aliquot of cells.

5. Swirl the transformation reactions gently to mix, then incubate the reactions on ice for 30 minutes.

6. Preheat NZY<sup>+</sup> broth (see Preparation of Media and Reagents) in a 42°C water bath for use in step 9.

   **Note** Transformation of XL10-Gold ultracompetent cells has been optimized using NZY<sup>+</sup> broth.

7. Heat-pulse the tubes in a 42°C water bath for 30 seconds. The duration of the heat pulse is critical for obtaining the highest efficiencies. Do not exceed 42°C.

   **Note** This heat pulse has been optimized for transformation in 14-ml BD Falcon polypropylene round-bottom tubes.

8. Incubate the tubes on ice for 2 minutes.
9. Add 0.5 ml of preheated (42°C) NZY broth to each tube and incubate the tubes at 37°C for 1 hour with shaking at 225–250 rpm.

10. Plate the appropriate volume of each transformation reaction, as indicated in the table below, on agar plates containing the appropriate antibiotic for the plasmid vector.

For the mutagenesis and transformation controls, spread cells on LB-ampicillin agar plates (see Preparation of Media and Reagents) that have been prepared with 80 μg/ml X-gal and 20 mM IPTG (see Preparing the Agar Plates for Color Screening).

### Transformation Reaction Plating Volumes

<table>
<thead>
<tr>
<th>Reaction Type</th>

</tr>
<tr>
<td>Mutagenesis control</td>
<td>10 μl</td>
</tr>
<tr>
<td>Transformation control (pUC 18)</td>
<td>5 μl</td>
</tr>
</tbody>
</table>

* When plating less than 100 μl from the transformation reaction, place a 100-μl pool of NZY broth on the agar plate, pipet the cells into the pool, then spread the mixture.

11. Incubate the transformation plates at 37°C for >16 hours.

### Expected Results for the Control Transformations

The expected colony number from the mutagenesis control transformation is between 50 and 800 colonies. Greater than 50% of colonies from the control mutagenesis transformation should contain all three mutations and appear as blue colonies on agar plates containing IPTG and X-gal.

**Note** The mutagenesis efficiency (ME) for the 4-kb QuikChange Multi control plasmid is calculated by the following formula:

$$ ME = \frac{\text{Number of blue colony forming units (cfu)}}{\text{Total number of colony forming units (cfu)}} \times 100\% $$

If transformation of the pUC18 control plasmid was performed, >100 colonies (>10⁹ cfu/μg) should be observed, with >98% having the blue phenotype.

### Expected Results for Transformation of the Experimental Mutagenesis

Expect between 10 and 1000 colonies, depending upon the number and nature of primers and the length and base composition of the DNA template used. For suggestions on increasing the colony number or mutagenesis efficiency, see Troubleshooting.
**XL10-GOLD ULTRACOMPETENT CELLS**

XL10-Gold ultracompetent cells feature the Hte phenotype, exhibiting increased transformation efficiencies with ligated DNA and large DNA molecules compared to most *E. coli* host strains. XL10-Gold cells are both endonuclease deficient (*endA1*) and recombination deficient (*recA*). The *endA1* mutation greatly improves the quality of plasmid miniprep DNA, and the *recA* mutation helps ensure insert stability. XL10-Gold cells grow faster than XL1- or XL2-Blue cells, resulting in larger colonies.

TRANSFORMATION GUIDELINES

It is important to store the XL10-Gold ultracompetent cells at –80°C to prevent a loss of efficiency. For best results, please follow the directions outlined in the following sections.

Storage Conditions

The XL10-Gold ultracompetent cells are very sensitive to even small variations in temperature and must be stored at the bottom of a –80°C freezer. Transferring tubes from one freezer to another may result in a loss of efficiency. The XL10-Gold ultracompetent cells should be placed at –80°C directly from the dry ice shipping container.

Aliquoting Cells

When aliquoting, keep the XL10-Gold ultracompetent cells on ice at all times. It is essential that the BD Falcon polypropylene tubes are placed on ice before the cells are thawed and that the cells are aliquoted directly into the prechilled tubes.

Use of 14-ml BD Falcon Polypropylene Round-Bottom Tubes

It is important that 14-ml BD Falcon polypropylene round-bottom tubes (BD Biosciences Catalog #352059) are used for the transformation protocol, since other tubes may be degraded by the β-mercaptoethanol during transformation. In addition, the duration of the heat-pulse step is critical and has been optimized specifically for the thickness and shape of these tubes.

Length and Temperature of the Heat Pulse

There is a defined window of highest efficiency resulting from the heat pulse during transformation. Optimal efficiencies are observed when cells are heat-pulsed for 30 seconds. Heat-pulsing for at least 30 seconds is recommended to allow for slight variations in the length of incubation. Efficiencies decrease when incubating for <30 seconds or for >40 seconds. Do not exceed 42°C.

Preparing Agar Plates for Color Screening

To prepare the LB agar plates for blue–white color screening, add 80 μg/ml of 5-bromo-4-chloro-3-indolyl-β-D-galactopyranoside (X-gal), 20 mM isopropyl-1-thio-β-D-galactopyranoside (IPTG), and the appropriate antibiotic to the LB agar. Alternatively, 100 μl of 10 mM IPTG and 100 μl of 2% X-gal (see Preparation of Media and Reagents) can be spread on the LB agar plates 30 minutes prior to plating the transformations. Prepare the IPTG in sterile dH₂O; prepare the X-gal in dimethylformamide (DMF). Do not mix the IPTG and the X-gal before pipetting them onto the plates because these chemicals may precipitate.
APPENDIX: GUIDELINES FOR CREATING ENGINEERED MUTANT CLONE COLLECTIONS

Optimizing Degenerate Primer Design
When designing primers containing degenerate codons, it is important to match the $T_m$s of the two primer sequences flanking the degenerate codon. If one side has a lower $T_m$ due to a lower GC content, extend the primer length on that side to increase the $T_m$. Sequences flanking the degenerate codon may differ in length by up to about 5 nucleotides. In addition to these considerations, follow the general primer design guidelines described in Mutagenic Primer Design.

Increasing Collection Representation and Size
In order to identify the best amino acid substitution(s) for a desired protein function, a mutant clone collection should contain all possible amino acid sequence permutations. The QuikChange Multi kit can be adapted to increase mutant collection representation and size by applying the suggestions listed in the table below.

<table>
<thead>
<tr>
<th>QuikChange Multi kit condition</th>
<th>Standard reaction specification</th>
<th>Suggested reaction specification for generating mutant clone collections</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mutagenesis reaction volume</td>
<td>25 μl</td>
<td>50–100 μl</td>
</tr>
<tr>
<td>QuikSolution reagent concentration</td>
<td>0–3%</td>
<td>4–10%</td>
</tr>
<tr>
<td>DNA template amount</td>
<td>50–100 ng</td>
<td>300 ng</td>
</tr>
<tr>
<td>$Dpn$ I digestion time</td>
<td>1 hour</td>
<td>2–3 hours</td>
</tr>
<tr>
<td>Competent cell type</td>
<td>XL10-Gold ultracompetent cells</td>
<td>Electroporation competent cells [e.g., ElectroTen-Blue electroporation competent cells (Stratagene Catalog #200159)]$^a,b$</td>
</tr>
</tbody>
</table>

$^a$ The ElectroTen-Blue electroporation competent cells are specifically designed for transforming large, ligated DNA. Therefore, ElectroTen-Blue competent cells are recommended for this transformation in order to increase mutant collection size and representation.

$^b$ Addition of a spin column purification step is recommended to remove excess salt from the DNA prior to transformation, as electroporation-competent cells can be sensitive to salts [e.g., use StrataPrep PCR purification kits (Stratagene Catalog #400771 or 400773)].

Suggestions for Adjusting Individual Site Mutation Efficiencies
It is possible to adjust the mutation efficiency at each site by varying primer concentrations. The appropriate amounts of each primer required to achieve the desired mutation efficiencies need to be determined empirically for each primer-template system. Start with 100 ng of each primer for 1–3 primers or 50 ng of each primer for 4–5 primers, and vary the amount from 2- to 10-fold depending on the system and the desired result.
**Troubleshooting**

When used according to the guidelines outlined in this instruction manual, this kit will provide a reliable means to conduct site-directed mutagenesis at multiple sites using ds-DNA templates. Variations in the base composition and length of primers, in length of the DNA template and in the thermal cycler may contribute to differences in mutagenesis efficiency. Refer to the following guidelines for troubleshooting the recovery of fewer than expected mutagenized plasmids.

<table>
<thead>
<tr>
<th>Observation</th>
<th>Suggestion(s)</th>
</tr>
</thead>
</table>
| Low transformation efficiency or low colony number | Ensure that sufficient DNA template is used in the mutagenesis reaction. Visualize the DNA template on a gel to verify the quantity and quality.  
Ensure that competent cells are stored at the bottom of a –80°C freezer immediately upon arrival (see also Transformation Guidelines). Test the efficiency of the competent cells using the pUC18 control plasmid.  
Ensure that mineral oil is not transferred into the transformation reaction when pipetting the *Dpn* I-treated DNA. Using the smallest pipet tips available, insert the pipet tip completely below the mineral oil overlay and clear the pipet tip while it is submerged beneath the overlay before collecting the sample.  
Increase the amount of the *Dpn* I-treated DNA used in the transformation reaction to 4 μl. Alternatively, ethanol precipitate the *Dpn* I digestion reaction, then resuspend and transform with the entire sample. |
| Low mutagenesis efficiency or low colony number with the control reaction | Different thermal cyclers may vary in ramping efficiencies. Optimize the cycling parameters for the control reaction, then repeat the protocol for the mutagenesis reactions.  
Verify that the agar plates were prepared correctly. See Preparing the Agar Plates for Color Screening, and follow the recommendations for IPTG and X-Gal concentrations carefully.  
For best visualization of the blue (β-gal+) phenotype, the control plates must be incubated for at least 1.6 hours at 37°C.  
Avoid multiple freeze-thaw cycles for the dNTP mix. Thaw the dNTP mix once, prepare single-use aliquots, and store the aliquots at –20°C. |
| Low mutagenesis efficiency with the experimental mutagenesis reaction(s) | Add the *Dpn* I restriction enzyme below the mineral oil overlay and ensure proper mixing of all components (especially the *Dpn* I) in the reaction.  
Allow sufficient time for the *Dpn* I to completely digest the parental template; repeat the digestion if too much DNA template was present.  
Titrate the amounts of primer and template added to the thermal cycling reaction.  
Verify that the template DNA was isolated from a *dam*+ *E. coli* strain. Plasmid DNA isolated from *dam*– strains, such as JM110 or SCS100, lacks methylation and is not digested by *Dpn* I.  
If mutagenesis efficiency remains low (<30%) after addressing other possibilities, redesign mutagenic primers to bind to the opposite strand of the plasmid. |
| Low colony number or low mutagenesis efficiency for long templates (>5 kb) | Titrate the amount of QuikSolution added from 0 to 1.5 μl per 25-μl mutant strand synthesis reaction. For most long templates, up to 0.75 μl of QuikSolution is optimal, but for certain long templates, including up to 1.5 μl of QuikSolution may increase recovery of the desired mutants.  
Mutagenesis of long templates may require optimization of the amounts of template and primers added to the thermal cycling reaction.  
Transformation efficiency will decrease as plasmid size increases. Transform XL10-Gold Ultracompetent Cells with up to 4 μl of the mutagenesis reaction, and plate a larger proportion of the transformation reaction. |

### Preparation of Media and Reagents

#### LB Agar (per Liter)
- 10 g of NaCl
- 10 g of tryptone
- 5 g of yeast extract
- 20 g of agar
- Add deionized H<sub>2</sub>O to a final volume of 1 liter
- Adjust pH to 7.0 with 5 N NaOH
- Autoclave
- Pour into petri dishes (~25 ml/100-mm plate)

#### NZY<sup>+</sup> Broth (per Liter)
- 10 g of NZ amine (casein hydrolysate)
- 5 g of yeast extract
- 5 g of NaCl
- Add deionized H<sub>2</sub>O to a final volume of 1 liter
- Adjust to pH 7.5 using NaOH
- Autoclave
- Add the following sterile-sterilized supplements prior to use:
  - 12.5 ml of 1 M MgCl<sub>2</sub>
  - 12.5 ml of 1 M MgSO<sub>4</sub>
  - 20 ml of 20% (w/v) glucose (or 10 ml of 2 M glucose)

#### LB–Ampicillin Agar (per Liter)
- 1 liter of LB agar, autoclaved
- Cool to 55°C
- Add 10 ml of 10-mg/ml filter-sterilized ampicillin
- Pour into petri dishes (~25 ml/100-mm plate)

#### TE Buffer
- 10 mM Tris-HCl (pH 7.5)
- 1 mM EDTA

#### 10 mM IPTG (per 10 ml)
- 24 mg of isopropyl-1-thio-β-D-galactopyranoside (IPTG)
- 10 ml of sterile dH<sub>2</sub>O
- Spread 100 μl per LB-agar plate

#### 2% X-Gal (per 10 ml)
- 0.2 g of 5-bromo-4-chloro-3-indolyl-β-D-galactopyranoside (X-Gal)
- 10 ml of dimethylformamide (DMF)
- Store at –20°C
- Spread 100 μl per LB-agar plate

MSDS INFORMATION

The Material Safety Data Sheet (MSDS) information for Stratagene products is provided on the web at [http://www.stratagene.com/MSDS/](http://www.stratagene.com/MSDS/). Simply enter the catalog number to retrieve any associated MSDS’s in a print-ready format. MSDS documents are not included with product shipments.
QUICK-REFERENCE PROTOCOL

- Prepare mutant strand synthesis reaction(s) in thin-walled tubes as indicated below:

**Control Reaction**
- 2.5 μl 10× Reaction Buffer
- 1 μl control template
- 1 μl control primer mix
- 1 μl dNTP mix
- 1 μl QuikChange Multi enzyme blend
- 18.5 μl ddH₂O

**Mutagenesis Reactions**
- 2.5 μl 10× Reaction Buffer
- X μl ds-DNA template (50 ng for ≤5 kb, or 100 ng for >5 kb*)
- X μl each primer (100 ng each for 1–3 primers or 50 ng each for 4–5 primers)
- 1 μl dNTP mix
- 1 μl QuikChange Multi enzyme blend
- ddH₂O to a final volume of 25 μl

* For templates >5 kb, also add 0–0.75 μl QuikSolution to the reaction (titrate the QuikSolution to determine optimal amount).

- If the thermal cycler to be used does not have a hot-top assembly, overlay each reaction with ~30 μl of mineral oil

- Cycle the reactions using the cycling parameters outlined in the following table:

<table>
<thead>
<tr>
<th>Segment</th>
<th>Cycles</th>
<th>Temperature</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>95°C</td>
<td>1 minute</td>
</tr>
<tr>
<td>2</td>
<td>30</td>
<td>95°C</td>
<td>1 minute</td>
</tr>
<tr>
<td></td>
<td></td>
<td>55°C</td>
<td>1 minute</td>
</tr>
<tr>
<td></td>
<td></td>
<td>65°C</td>
<td>2 minutes/kb of plasmid length</td>
</tr>
</tbody>
</table>

- Add 1 μl of Dpn I restriction enzyme below the mineral oil overlay (if used)

- Gently and thoroughly mix each reaction, spin down in a microcentrifuge for 1 minute, and immediately incubate at 37°C for 1 hour to digest parental DNA

- Transform 1.5 μl of the Dpn I-treated DNA into a 45-μl aliquot of XL10-Gold ultracompetent cells (see Transformation of XL10-Gold Ultracompetent Cells in the instruction manual)
